---

---

---

---

---

---

---

## Why do birds display colorful plumage?

- Theory of honest signals – to provide reliable information about the **quality** of an individual (Darwin 1871, Andersson 1994)
- Typically males display and compete; females choose
- Males of many species display multiple plumage ornaments (Møller and Pomianski 1993)

---

---

---

---

---

---

---

---

---

---

## Why possess multiple ornaments?

- 1) Send multiple messages (about different qualities),
- 2) Send redundant messages (about overall quality), or
- 3) Because females simply prefer some plumage traits (via runaway selection)

Several mechanisms may allow for multiple messages:

- a) Plumage ornaments of different metabolic origin may reflect different intrinsic (production) or extrinsic (social) costs to the individual (Searcy and Nowicki 2005)
- b) Environmental/habitat contingency; environmental conditions may render some signals more effective (Roulin et al. 2008)

---

---

---

---

---

---

---

---

---

---

## What is individual "quality"?

- Any phenotypic or genotypic trait directly related to individual fitness (i.e., survival or reproduction) (Wilson and Nussey 2010)

### Measures of individual quality could include:

- Body condition
- Foraging ability
- # of fledglings produced
- Immunocompetence
- Age/survival

---

---

---

---

---

---

---

---

---

---

---

---

## Mechanisms of avian coloration

- Can be created by pigments, physical structure, or a combination (Hill and McGraw 2006)
- Carotenoids** – produce reds, yellows, and greens
- Melanins** – produce black, gray, brown, buff, and some yellows
- Structural** – produce blues, some greens, iridescence and glossiness (and whites)

---

---

---

---

---

---

---

---

---

---

---

---

## Plumage ornaments

May signal quality in relation to:

- Size of feather patch (Senar 2006)
- Color variables of feather patch (Montgomery 2006)
  - Brightness – Total reflectance
  - Hue – Wavelength of peak reflectance
  - Chroma – Proportion of reflectance located in a specific region (e.g., Blue-Green) of the color spectrum

---

---

---

---

---

---

---

---

---

---

---

---

**Cerulean Warbler blue – Structural**

---

---

---

---

---

---

---

---

**Breast band – Eumelanin**

---

---

---

---

---

---

---

---

**White tail spots – Achromatic**

---

---

---

---

---

---

---

---

### Three research questions

- 1) Do Cerulean Warbler plumage ornaments act as honest indicators of quality? If so, do they send multiple messages or redundant messages?
- 2) Does habitat heterogeneity impact information content of ornaments (and if so, how)?
- 3) Do birds that display differential elaboration of plumage ornaments inhabit different habitats?

---

---

---

---

---

---

---

---

### Importance and novelty

- Canopy-dwelling species with unique plumage which occupies unique light environment  
(Théry 2006)
- Assessed three potential plumage ornaments of different metabolic origin
- Evaluated relationship between habitat conditions and signaling system

---

---

---

---

---

---

---

---

### Methods - Habitat manipulations

Basal area: 28.4 – 6.5 m<sup>2</sup>/ha

---

---

---

---

---

---

---

---

### Capturing CERW

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Nest searching and videography

---

---

---

---

---

---

---

---

## Lab - Plumage measurements

---

---

---

---

---

---

---

---

## Lab - Quality measurements

---

---

---

---

---

---

---

---

## Measured

### Plumage (Response variables):

- Crown and rump blue-green (435 – 534 nm) hue and chroma
- Breast band width
- Tail white

### vs. Quality measures (Predictors):

- Age (SY vs. ASY) - ANOVA
- Current body condition (body mass)
- Condition at molt (via ptilochronology)
- Parental ability (feeding rate/hr/nestling)

and

- Habitat characteristics (basal area)

Multiple regression

---

---

---

---

---

---

---

---

## Results – Redundant messages

- All plumage ornaments signaled age (SY vs. ASY)

---

---

---

---

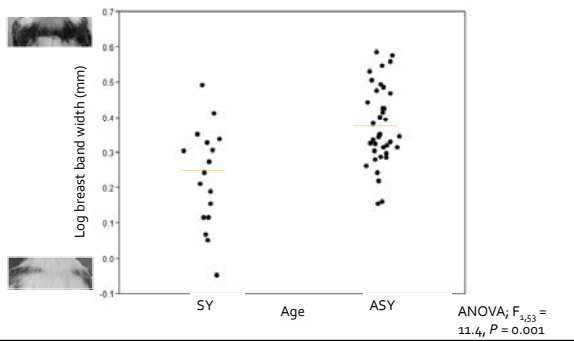

---

---

---

---

## Breast band width

---

---

---

---

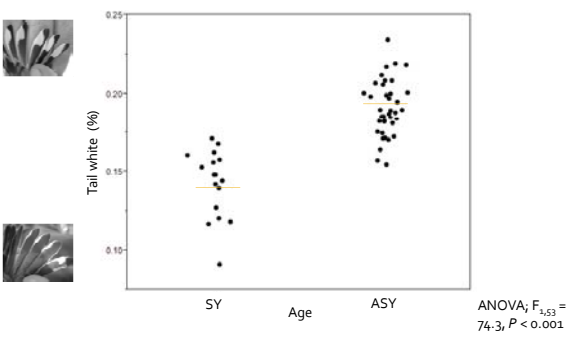

---

---

---

---

## Tail white

---

---

---

---

---

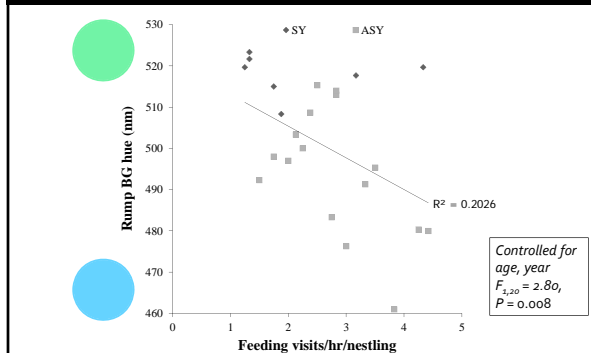

---

---

---

## Multiple messages – Rump

---

---

---

---

---

---

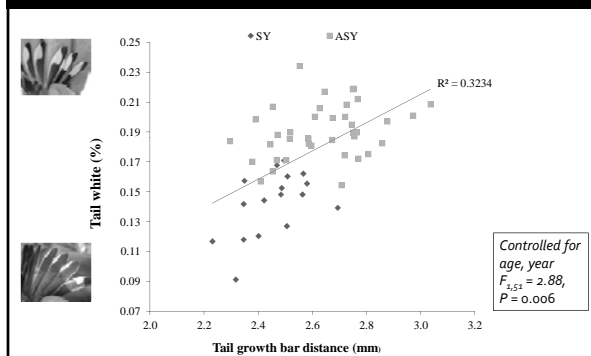

---

---

---

---

## Tail white

---

---

---

---

---

---

---

---

---

---

## Breast band width

- No initial relationship between breast band and any quality measure, however...
- Habitat contingent relationship between breast band width and body mass (i.e., significant interaction between body mass and basal area)
- Only in **moderately-open** habitats did we observe a significant relationship
- The most densely populated habitat as well

---

---

---

---

---

---

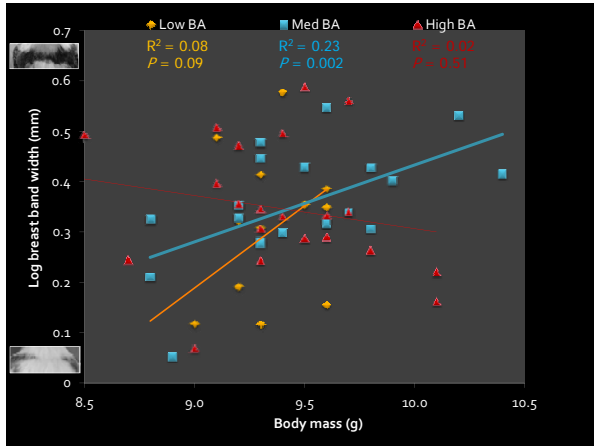

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Why might habitat contingency exist?

- Eumelanin production regulated by melanocortin system (Roulin and Ducrest 2011)
- This system of hormones is also responsible for aggressiveness, competitive ability, and stress response
- Melanogenesis is genetically linked to these other traits (pleiotropy)
- Elaboration of melanin plumage signals an ability to compete and respond to stress
- In high-density habitats, individuals with smaller breast bands may be challenged by conspecific males, increasing stress and making it difficult to maintain condition

---

---

---

---

---

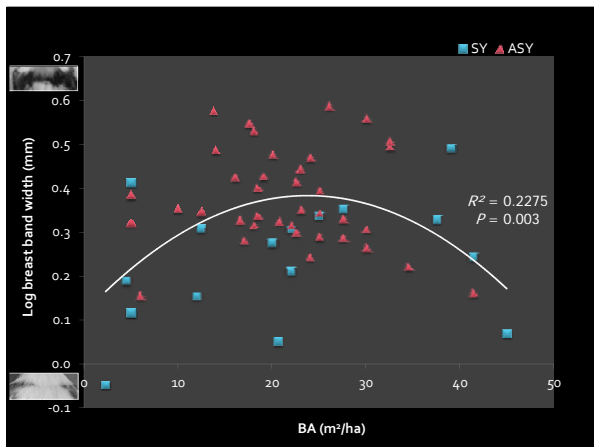

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

## Summary

- Support for redundant and multiple message hypotheses
- All plumage ornaments signaled age (to differing extents)
- Tail white signaled condition at molt (long-term quality)
- Rump chroma signaled provisioning rate (good parent hypothesis, Møller and Thornhill 1998)
- Breast band width signaled current body condition but ONLY in moderately open habitat, likely related to competitive ability of those birds (related to pleiotropic effects, Roulin and Ducrest 2011)
- Birds with larger breast bands distributed non-randomly; found more often in high-density, moderately open forest
